

VLTI and extragalactic science

Huub Röttgering
Leiden Observatory/NEVEC

Overview

- Observations and theories
 - Galaxies
 - Active galaxies
- 10 micron MIDI observations of nearby AGN
- Prima observations of distant radio loud and radio quiet ellipticals
- Conclusions

Issues related to galaxy formation

- How do galaxies work?
 - Dynamics of the gas (cold, warm and hot), dust, magnetic fields and stars
 - Distribution of starformation
- When and how do galaxies form?
- Why are there elliptical galaxies and spiral galaxies?
- How and why are these galaxies clustered?

Ingredients for a proper theory

- Gravitational collapse of dark matter halos
- Gas cooling in dark matter halos
- Star formation in dense regions with cool gas
- Feedback from supernovae
- Merging of dwarf galaxies to form bigger galaxies

Issues

- How and when do massive black holes form?
- Why does every galaxy seem to have a massive central blackhole?
- Physics of active galaxies?

MIDI observations of nearby Active galaxies

- MIDI: 10 micron VLTI instrument
- Observe emission from the few 100 K dust torus to constrain size and orientation of tori
- Work plan (PhD Bjorn Heijligers)
 - Compile a list of candidates
 - Imaging at 10 micron using TIMMI2: resolution of 0.5 arcsec
 - VLT AO imaging at 5 micron using NAOS: resolution 0.1 arcsec
 - Using these observations to constrain torus models
 - Pick best candidates for MIDI observations

Arcsec

Models of dusty tori

- Radiative transfer model (Granato and Danese)
 - Axially symmetric toroidal Structure
 - Composed of Galactic dust
 - Radiative transfer for Emission, Absorption, Scattering and grain destruction
- Input
 - Luminosity of the central quasar
- Output
 - Spectral energy distribution
 - ``Maps''

Spectral energy distribution

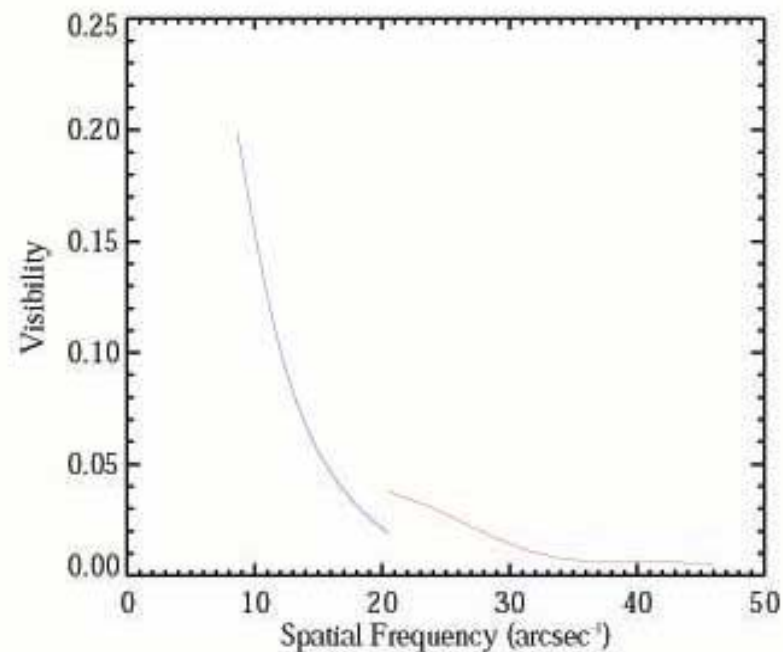

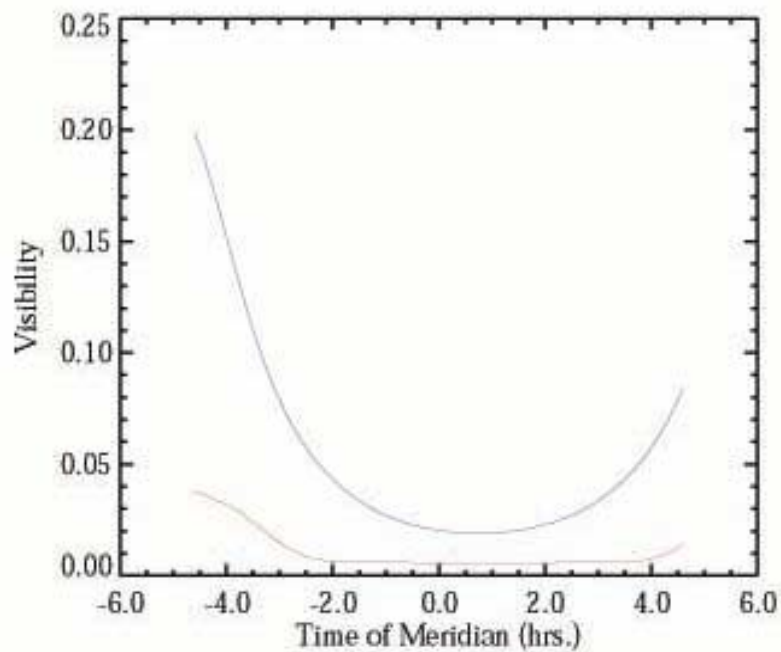

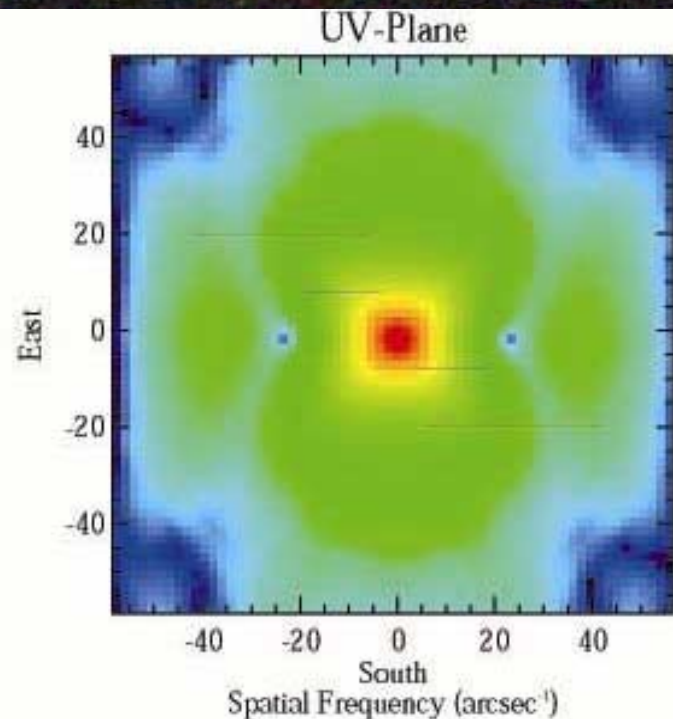

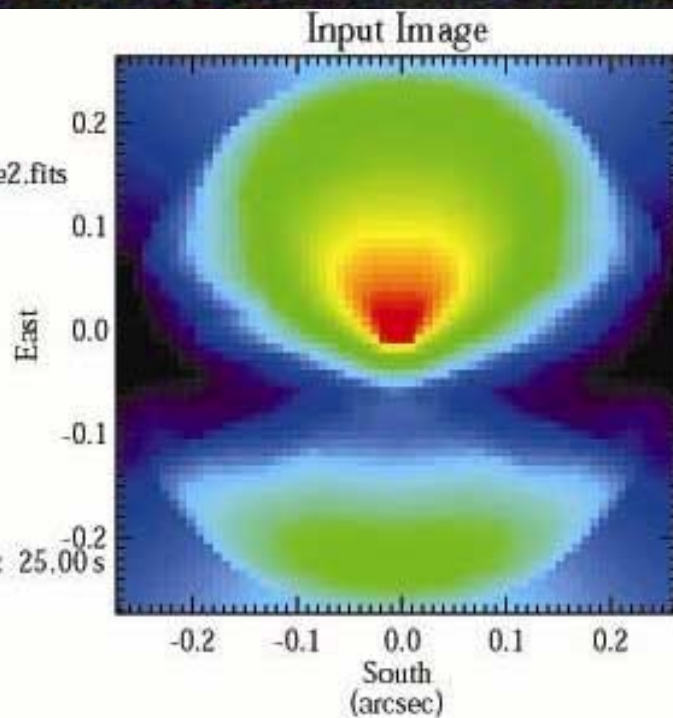

Input File Name:
C:\users\Phd\AGN\nice2.fits

Frame: 1 (10.0 μm)

Baseline Key:
UT1 -- UT2
UT1 -- UT3

Total Integration Time: 25.00 s

Models of radial profiles of elliptical galaxies

Profiles of cores of ellipticals

- Why such a rich variation of these profiles ?
 - Dynamics stars ?
 - Formation history ?
 - Presence of massive black-hole ?
 - Presence radio source?
- VLTI: measure accurately inner profiles of radio loud and radio quiet ellipticals
 - Range of galaxy type and redshifts
 - Near IR:
 - Interferometry relatively easy
 - Peak of the spectral energy distribution of stars
 - Surface brightness of (distant) galaxies faint: Use PRIMA+ VLT
 - Define a samples of galaxies close to bright stars

 RMS noise 0.162 mJy

Conclusion

VLTI will be the first instrument to carry out high resolution optical interferometry on extragalactic objects
